

**Instructions.** You have 60 minutes. Closed book, closed notes, and no calculators allowed. *Show all your work* in order to receive full credit.

1. Consider points  $A(4, -3, 2)$  and  $B(2, 1, c)$  and vectors  $\mathbf{u} = \langle 1, -2, 3 \rangle$  and  $\mathbf{v} = \langle -1, -1, 2 \rangle$ .

- (a) Find the vector projection of  $\mathbf{u}$  along  $\mathbf{v}$ .

*Solution:*

$$\begin{aligned} \text{proj}_{\mathbf{v}} \mathbf{u} &= \frac{\mathbf{u} \cdot \mathbf{v}}{\|\mathbf{v}\|^2} \mathbf{v} = \frac{\langle 1, -2, 3 \rangle \cdot \langle -1, -1, 2 \rangle}{1 + 1 + 4} \langle -1, -1, 2 \rangle = \frac{1(-1) - 2(-1) + 3(2)}{6} \langle -1, -1, 2 \rangle \\ &= \frac{-1 + 2 + 6}{6} \langle -1, -1, 2 \rangle = \frac{7}{6} \langle -1, -1, 2 \rangle = \boxed{\left\langle \frac{-7}{6}, \frac{-7}{6}, \frac{7}{3} \right\rangle} \end{aligned}$$

- (b) Find the area of the parallelogram with adjacent sides  $\mathbf{u}$  and  $\mathbf{v}$ .

*Solution:* The area of the parallelogram is  $\|\mathbf{u} \times \mathbf{v}\|$ . So we have:

$$\begin{aligned} \mathbf{u} \times \mathbf{v} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -2 & 3 \\ -1 & -1 & 2 \end{vmatrix} = \langle -2(2) + 1(3), -(1(2) + 1(3)), 1(-1) + 1(-2) \rangle = \langle -1, -5, -3 \rangle \\ \Rightarrow A &= \|\mathbf{u} \times \mathbf{v}\| = \sqrt{1 + 25 + 9} = \boxed{\sqrt{35}}. \end{aligned}$$

- (c) Find all values of  $c$  such that the length of  $\overrightarrow{AB}$  equals 5.

*Solution:* We have

$$\overrightarrow{AB} = \langle -2, 4, c - 2 \rangle.$$

So,

$$\begin{aligned} \|\overrightarrow{AB}\| = 5 &\iff \sqrt{4 + 16 + (c - 2)^2} = 5 \iff 20 + (c - 2)^2 = 25 \\ &\iff (c - 2)^2 = 5 \iff \boxed{c = 2 \pm \sqrt{5}}. \end{aligned}$$

- (d) Find all values of  $c$  such that  $\overrightarrow{AB}$  is parallel to  $\mathbf{u}$ .

*Solution:*  $\overrightarrow{AB}$  is parallel to  $\mathbf{u}$  if there exists a real nonzero number  $k$  such that:

$$\overrightarrow{AB} = k\mathbf{u} \iff \begin{cases} -2 = k(1) \\ 4 = k(-2) \\ c - 2 = k(3) \end{cases}$$

From the first two equations, we get  $k = -2$  and plugging it into the third, we have:

$$c - 2 = (-2)(3) \iff \boxed{c = -4}.$$

- (e) Find all values of  $c$  such that  $\overrightarrow{AB}$  is orthogonal to  $\mathbf{v}$ .

*Solution:* The vectors are orthogonal if their dot product is zero. So we have:

$$\begin{aligned} \overrightarrow{AB} \cdot \mathbf{v} = 0 &\iff \langle -2, 4, c - 2 \rangle \cdot \langle -1, -1, 2 \rangle = 0 \iff -2(-1) + 4(-1) + 2(c - 2) = 0 \\ &\iff 2 - 4 + 2c - 4 = 0 \iff 2c = 6 \iff \boxed{c = 3}. \end{aligned}$$

2. Below is a sketch of the space curve:

$$\mathbf{r}(t) = \langle t \cos t, t \sin t, t \rangle, \quad 0 \leq t \leq \frac{7\pi}{3}.$$

*Solution:*

(a) Draw on the above the position and velocity vectors for  $t = \frac{3\pi}{2}$ .

*Solution:* We need to compute both  $\mathbf{r}\left(\frac{3\pi}{2}\right)$  and  $\mathbf{r}'\left(\frac{3\pi}{2}\right)$  then draw the first in standard position and the second starting at the tip of the first.

$$\begin{aligned} \mathbf{r}\left(\frac{3\pi}{2}\right) &= \left\langle 0, -\frac{3\pi}{2}, \frac{3\pi}{2} \right\rangle \\ \mathbf{r}'(t) &= \langle \cos t - t \sin t, \sin t + t \cos t, 1 \rangle \\ \Rightarrow \mathbf{r}'\left(\frac{3\pi}{2}\right) &= \left\langle \frac{3\pi}{2}, -1, 1 \right\rangle \end{aligned}$$

(b) Find the speed at time  $t$  and simplify your result.

*Solution:*

$$\begin{aligned} \|\mathbf{r}'(t)\| &= \sqrt{(\cos t - t \sin t)^2 + (\sin t + t \cos t)^2 + 1} \\ &= \sqrt{\cos^2 t - 2t \cos t \sin t + t^2 \sin^2 t + \sin^2 t + 2t \cos t \sin t + t^2 \cos^2 t + 1} \\ &= \sqrt{1 + t^2(\sin^2 t + \cos^2 t) + 1} = \boxed{\sqrt{t^2 + 2}} \end{aligned}$$

(c) At what time(s) is the acceleration horizontal (i.e. normal to  $\mathbf{k}$ )?

*Solution:* We need to solve for  $t$  in  $\mathbf{r}''(t) \cdot \mathbf{k} = 0$  but any dot product with  $\mathbf{k} = \langle 0, 0, 1 \rangle$  only leaves you with the  $z$ -component of the vector. Here, since the  $z$ -component in  $\mathbf{r}'(t)$  is constant, then the  $z$ -component of  $\mathbf{r}''(t)$  is zero for all  $t$ . So the acceleration is horizontal for all times  $t$ .

3. Time to sketch some surfaces!

- (a) For  $x^2 + \frac{y^2}{4} - z^2 = -1$ , sketch the given traces, then the surface in 3D.

*Solution:*

- (b) Sketch the surface  $y = z^2 + 1$ .

*Solution:*

4. Consider the following point, line, and plane:

$$A = (3, -2, 5),$$

$$\vec{\ell}(t) = \langle 1 - 2t, t, 3 + 4t \rangle,$$

$$P: 2x - 3y + z = -4,$$

(a) Give the equation of a plane parallel to the plane  $P$  that passes through  $A$ .

*Solution:* The plane will have the same normal as  $P$ , i.e.  $\mathbf{n} = \langle 2, -3, 1 \rangle$  and so using point  $A$ , we have:

$$2(x - 3) - 3(y + 2) + (z - 5) = 0 \iff \boxed{2x - 3y + z = 17}.$$

(b) Find the point of intersection of the line  $\vec{\ell}(t)$  and the plane  $P$ .

*Solution:* Plug in the coordinates of the line  $\vec{\ell}(t)$  into the plane and solve for  $t$ :

$$\begin{aligned} 2(1 - t) - 3(t) + (3 + 4t) &= -4 \iff 2 - \cancel{2t} - 3t + 3 + \cancel{4t} = -4 \\ &\iff -3t = -9 \iff t = 3 \end{aligned}$$

So the position vector for the point is  $\vec{\ell}(3)$  and thus in coordinate notation the point is  $\boxed{(-5, 3, 15)}$ .

(c) Find the angle the line  $\vec{\ell}(t)$  makes with the normal to the plane  $P$ . (Your answer may involve an inverse trigonometric function.)

*Solution:* We need to consider the angle between the direction vector of the line:  $\mathbf{u} = \langle -2, 1, 4 \rangle$  and the normal  $\mathbf{n} = \langle 2, -3, 1 \rangle$  to the plane. We have:

$$\begin{aligned} \cos \theta &= \frac{\mathbf{u} \cdot \mathbf{n}}{\|\mathbf{u}\| \|\mathbf{n}\|} = \frac{\langle -2, 1, 4 \rangle \cdot \langle 2, -3, 1 \rangle}{\sqrt{4 + 1 + 16} \sqrt{4 + 9 + 1}} \\ &= \frac{-2(2) + 1(-3) + 4(1)}{\sqrt{21} \sqrt{14}} = \frac{-\cancel{4} - 3 + \cancel{4}}{7\sqrt{3}\sqrt{2}} \\ &= \frac{-3}{7\sqrt{6}} = -\frac{3\sqrt{6}}{7(6)} = -\frac{\sqrt{6}}{14} \implies \theta = \arccos\left(-\frac{\sqrt{6}}{14}\right) \end{aligned}$$

(d) Find an equation for the plane containing the point  $A$  and the line  $\vec{\ell}(t)$ .

*Solution:* We need two nonparallel vectors in the plane to cross. We already have  $\mathbf{u} = \langle -2, 1, 4 \rangle$  from the line, so now we pick a point  $B(1, 0, 3)$  from the line to form  $\vec{AB} = \langle -2, 2, -2 \rangle = -2 \langle 1, -1, 1 \rangle$ . So a normal vector to the plane is:

$$\vec{AB} \times \mathbf{u} = -2 \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -1 & 1 \\ -2 & 1 & 4 \end{vmatrix} = -2 \langle -4 - 1, -(4 + 2), 1 - 2 \rangle = -2 \langle -5, -6, -1 \rangle$$

and taking the scalar multiple  $\langle 5, 6, 1 \rangle$ , we have the equation of the plane as:

$$\boxed{5(x - 3) + 6(y + 2) + z - 5 = 0} \quad \text{or} \quad \boxed{5x + 6y + z = 8}.$$

5. A bicycle pedal is attached to a 17 cm crank. When the crank is at an angle of  $30^\circ$  with the vertical (as shown) a foot applies a downward force of 200 N.

- (a) What is the resulting torque? Give your answer as a vector.

*Solution:* Set up the force as  $\mathbf{G} = \langle 0, -200 \rangle = -200 \langle 0, 1 \rangle$  and then along the crank

$$\vec{PQ} = \langle 0.17 \cos(120^\circ), 0.17 \sin(120^\circ) \rangle = 0.17 \left\langle -\frac{1}{2}, \frac{\sqrt{3}}{2} \right\rangle = \frac{0.17}{2} \langle -1, \sqrt{3} \rangle.$$

Then add a zero  $\mathbf{k}$ -component to both to take the cross product for the torque:

$$\begin{aligned} \vec{\tau} &= \vec{PQ} \times \mathbf{G} = \frac{-200(0.17)}{2} \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & \sqrt{3} & 0 \\ 0 & 1 & 0 \end{vmatrix} = -100(0.17) \langle 0, 0, -1 - 0 \rangle \\ &= -17 \langle 0, 0, -1 \rangle = \boxed{17\mathbf{k} = \langle 0, 0, 17 \rangle}. \end{aligned}$$

- (b) What is the magnitude of the torque? Indicate units.

*Solution:*

$$\|\vec{\tau}\| = \sqrt{0 + 0 + 17^2} = \boxed{17 \text{ Nm}}$$

- (c) What is the direction of the torque vector? (Into the page  $\otimes$ , or out of the page  $\odot$ , in the figure).

*Solution:* By the right hand rule, the torque is coming out of the page, i.e.  $\odot$ .

6. An object moves in the plane with acceleration

$$\mathbf{a}(t) = \left\langle \frac{1}{t^2}, \frac{t}{(1+t^2)^2} \right\rangle.$$

At time  $t = 1$  it is located at the point  $(1, 0)$  and has velocity  $\langle 2, 1 \rangle$ . Find a function  $\mathbf{r}(t)$  giving its position at all times  $t > 0$ .

*Solution:* We start integrating, first the acceleration to get the velocity for all times  $t > 0$ :

$$\begin{aligned} \mathbf{a}(t) &= \left\langle \frac{1}{t^2}, \frac{t}{(1+t^2)^2} \right\rangle \\ \Rightarrow \mathbf{v}(t) - \mathbf{v}(1) &= \int_1^t \left\langle \frac{1}{u^2}, \frac{u}{(1+u^2)^2} \right\rangle du = \left\langle -\frac{1}{u}, -\frac{1}{2(1+u^2)} \right\rangle \Big|_{u=1}^{u=t} \\ &= \left\langle -\frac{1}{t}, -\frac{1}{2(1+t^2)} \right\rangle - \left\langle -1, -\frac{1}{4} \right\rangle = \left\langle -\frac{1}{t}, -\frac{1}{2(1+t^2)} \right\rangle + \left\langle 1, \frac{1}{4} \right\rangle \\ \Leftrightarrow \mathbf{v}(t) &= \left\langle -\frac{1}{t}, -\frac{1}{2(1+t^2)} \right\rangle + \left\langle 1, \frac{1}{4} \right\rangle + \langle 2, 1 \rangle = \left\langle 3 - \frac{1}{t}, \frac{5}{4} - \frac{1}{2(1+t^2)} \right\rangle \\ \Rightarrow \mathbf{r}(t) - \mathbf{r}(1) &= \int_1^t \left\langle 3 - \frac{1}{u}, \frac{5}{4} - \frac{1}{2(1+u^2)} \right\rangle du = \left\langle 3u - \ln|u|, \frac{5u}{4} - \frac{1}{2} \arctan u \right\rangle \Big|_{u=1}^{u=t} \\ &= \left\langle 3t - \ln t, \frac{5t}{4} - \frac{1}{2} \arctan t \right\rangle - \left\langle 3 - 0, \frac{5}{4} - \frac{1}{2} \left(\frac{\pi}{4}\right) \right\rangle \\ \Leftrightarrow \mathbf{r}(t) &= \left\langle 3t - \ln t, \frac{5t}{4} - \frac{1}{2} \arctan t \right\rangle - \left\langle 3, \frac{5}{4} - \frac{\pi}{8} \right\rangle + \langle 1, 0 \rangle \\ \Rightarrow \mathbf{r}(t) &= \boxed{\left\langle 3t - \ln t - 2, \frac{5}{4}(t - 1) - \frac{1}{2} \arctan t + \frac{\pi}{8} \right\rangle} \end{aligned}$$

7. A particle moves with *velocity*  $\mathbf{v}(t) = \langle t^2, 2t, 2 \rangle$ .

(a) Find the distance the particle travels between times  $t = 1$  and 2.

*Solution:* The distance is the integral of the speed over time and since the speed is:

$$\|\mathbf{v}(t)\| = \sqrt{t^4 + 4t^2 + 4} = \sqrt{(t^2 + 2)^2} = |t^2 + 2| = t^2 + 2$$

then the distance traveled is:

$$\begin{aligned} L &= \int_1^2 \|\mathbf{v}(t)\| dt = \int_1^2 t^2 + 2 dt \\ &= \left[ \frac{t^3}{3} + 2t \right]_1^2 = \frac{8}{3} + 4 - \left( \frac{1}{3} + 2 \right) = \frac{7}{3} + 2 = \boxed{\frac{13}{3}} \end{aligned}$$

(b) Calculate the curvature of the trajectory at time  $t = 1$ .

*Solution:* The acceleration at time  $t$  is  $\mathbf{a}(t) = \mathbf{v}'(t) = \langle 2t, 2, 0 \rangle$  and so plugging in at  $t = 1$ , we have:

$$\mathbf{v}(1) = \langle 1, 2, 2 \rangle \quad , \quad \mathbf{a}(1) = \langle 2, 2, 0 \rangle = 2 \langle 1, 1, 0 \rangle \quad , \quad \|\mathbf{v}(1)\| = t^2 + 2 \Big|_{t=1} = 3$$

and the cross product is:

$$\mathbf{v}(1) \times \mathbf{a}(1) = 2 \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 2 \\ 1 & 1 & 0 \end{vmatrix} = 2 \langle 0 - 2, -(0 - 2), 1 - 2 \rangle = 2 \langle -2, 2, -1 \rangle.$$

Therefore, the curvature at  $t = 1$  is

$$\kappa(1) = \frac{\|\mathbf{v}(1) \times \mathbf{a}(1)\|}{\|\mathbf{v}(1)\|^3} = \frac{2\sqrt{4 + 4 + 1}}{3^3} = \frac{2(3)}{27} = \boxed{\frac{2}{9}}.$$

(c) **Extra Credit (5pts)** Find the unit tangent vector  $\mathbf{T}(t)$  and the tangential component of acceleration  $a_{\mathbf{T}}$  at  $t = 1$ .

*Solution:* The unit tangent vector is the normalized velocity vector:

$$\mathbf{T}(t) = \frac{\mathbf{v}(t)}{\|\mathbf{v}(t)\|} = \frac{\langle t^2, 2t, 2 \rangle}{t^2 + 2} = \left\langle \frac{t^2}{t^2 + 2}, \frac{2t}{t^2 + 2}, \frac{2}{t^2 + 2} \right\rangle \Rightarrow \boxed{\mathbf{T}(1) = \left\langle \frac{1}{3}, \frac{2}{3}, \frac{2}{3} \right\rangle}$$

and the tangential component of acceleration is:

$$a_{\mathbf{T}}(t) = \|\mathbf{v}(t)\|' = (t^2 + 2)' = 2t \Rightarrow \boxed{a_{\mathbf{T}}(1) = 2}.$$

We could also have used the formula:

$$a_{\mathbf{T}}(1) = \mathbf{a} \cdot \mathbf{T} \Big|_{t=1} = 2 \langle 1, 1, 0 \rangle \cdot \left\langle \frac{1}{3}, \frac{2}{3}, \frac{2}{3} \right\rangle = 2 \left( \frac{1}{3} + \frac{2}{3} + 0 \right) = 2. \quad \checkmark$$
